

## Parittoman lohkon kohtalo

Pelosta pöytään ja suuhun, ettei joudu suden suuhun.  
Se on elämisen ehto, yksi ainoa vaihtoehto.  
Kaskettiin lohkolta maahan pohjoiseen ja kylmään,  
Hallaperän perheviljelmään.  
Metsästä pelloksi, mustikasta mansikaksi.

Jokainen lohko kasvilajinsa löytää, vaikka kasvien  
kriteerit eivät anna löysää.  
Pienelle lohkolle tarjonta on köyhää,  
iso lohko sopivan parin löytää.  
Yksi lohko vaikuttaa kalanruodolta,  
ei kulje kylvökone tuolla ulkomuodolla.  
Rinnepellolla traktori on julmassa pulmassa,  
vain purjevene kulkee vinossa kulmassa.  
Näkyy tuvan ikkunasta paras kasvu,  
unohtuu Hallaperän kaukainen pohjoinen tasku.

Tutkimusreessä analyysi tekee koodinlukija,  
ja johtopäätöksiä vetää tutkija.  
Tuottavuus on toinen puoli,  
puuttuessaan melkoinen huoli.

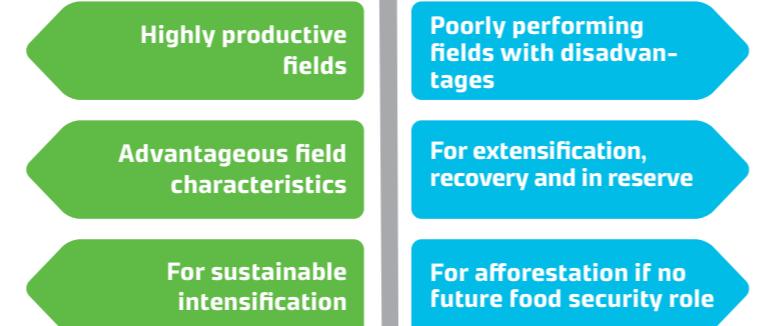

Kestääkö edes sosiaalinen puoli, vaikkei petä talouspuoli?  
Mikäli ympäristö kuoli, onko kohtalon sähkötuoli?

Tuli halla ja hukkakaura, ei maata käänny enää aura.  
Hevosheinää kasvaa Hallaperän lohkolta,  
pien kaunistaa kukkivat rohdot.  
Huippulohkoille lisää apulantaa,  
Hallaperän lohkoille Ryysyrantaa.

Totuusko pitäisi mykistää, ja kaikki tasapäistää?

Pelosta suuhun, pelosta puuhun.  
Elämisen ehto, puinen kehto.  
Pelosta suuhun, pelosta puuhun.  
Puinen ehto, elämän kehto.

Lauri Jauhainen

Land use  
optimization  
tool

## Land use optimization tool

## Classification of field parcels

Land use optimization tool helps the farmer to identify the best and weakest field parcels on the basis of several characteristics.

Land use optimization tool allocates virtually all field parcels in Finland either to sustainable intensification (green), extensification (red) or afforestation (dark red). Sustainably intensified fields are primarily used for food production, while extensified fields are allocated for greening purposes (green fallow, nature managed fields etc.) to increase landscape diversity and recover from soil compaction or any other imperfections. Afforested fields again have too many serious defects and therefore, lack any future role for food security.

The developed land use optimization tool is implemented for all Finnish farmers via the EconomyDoctor portal of the Natural Resources Institute Finland (Luke). The tool will be launched for farmers' use with strong authentication to safeguard privacy. Farmers may grant access to advisors and neighboring farmers. The tool is routinely updated automatically when new data appears, e.g. regarding the data on NDVI-based productivity gaps.

The tool has a three-step scoring system based on seven physical characteristics and the productivity of field parcels.

The first scoring round is based on the general physical characteristics of field parcels (parcel size, shape, slope, distance to the farm center) and the second round is based on productivity estimations that are calibrated using optical satellite NDVI-values estimated for each parcel and also on the proximity to waterways. The production capacity was assessed by using satellite data for different crops from critical growth stages to determine the total biomass.

The final third scoring round focuses on the soil type and on the logistic advantages for field operations. In the case of an organic peat soil type, a field parcel with a red light according to the second stage scoring round was determined as dark red in the third scoring round. This means that the land would be directed to afforestation. If the logistic advantages were found to be high for a field parcel with a yellow light from the second scoring round, and the soil type was other than organic peat, the field parcel was allocated for intensification instead of extensification even though it had some disadvantages.
